Jigsaw Drop and Picture Blast Overview

Gameplay systems and improvement directions

Research snapshot 23 October 2026

My main conclusion is that these games have a strong underlying interaction: **recognize an image, assemble it, clear it, and discover what becomes available next.** Their most interesting opportunity is to make that last step more meaningful—so that the player can understand and influence what happens next—while preserving the relaxed appeal of completing pictures.

Scope and confidence

I researched **Runyou's Jigsaw Drop: Solitaire Puzzle** and **Picture Blast Solitaire, published by Joyteractive on iOS and Gismart on Android**, using material available on **23 October 2026**. The inspected iOS versions were Jigsaw Drop **1.0.18** and Picture Blast **1.4.3**. Several similarly named games have different rules, so identifying the exact products matters. [1, 2, 3]

One limitation matters for your request for "every exact detail": **this is a public-evidence teardown, not an installed-app playtest.** I inspected official descriptions, release histories, event announcements, promotional screens, public reviews, and some gameplay-video thumbnails. Full gameplay recordings were not successfully viewable. Consequently, I distinguish documented features, visible interface details, player reports, and rules that remain unverified. Exact booster prices, unlock schedules, movement edge cases, and economy formulas cannot responsibly be filled in from genre conventions.

Part I — Gameplay and systems teardown

1. The shared gameplay structure

Both games revolve around **reconstructing pictures from fragments on an evolving board**. Completed pictures disappear, and additional pieces become available. The stock of hidden material makes the board change as the player solves it. That loop is explicit in the developers' descriptions. [4, 5]

The player's task can be understood as four layers:

Layer	What the player is doing	What can make it demanding
Recognition	Identifying fragments from the same image	Similar colors, faces, patterns, or objects
Spatial assembly	Putting those fragments in the correct relative positions	Larger images, awkward footprints, crowded layouts
Board management	Organizing unfinished images and available space	Movement restrictions, linked groups, limited useful destinations
Exposure planning	Deciding what to complete to reveal more material	Hidden stock, consequential clear locations, dependencies between images

The first two layers are directly supported by the advertised gameplay. The precise strength of the latter two depends on rules that are not fully documented publicly.

Why the loop can be satisfying

My interpretation is that the games distribute completion rewards across several scales.

A correct connection gives a small recognition payoff: *these belong together*. Finishing a picture provides a larger visual payoff. Finishing a level supplies a session boundary. Collections, events, and stories can then give those completed sessions a lasting destination.

This is a useful structure for short sessions because the player receives recognizable progress without needing to finish a large conventional jigsaw.

There is also an inherent tension: **the completed picture disappears just when it becomes fully understandable and attractive.** A good post-level display, gallery, or story can preserve that value. Without one, the image risks becoming disposable puzzle material.

2. Jigsaw Drop: Solitaire Puzzle

2.1 Board, input, and picture assembly

The official promotional examples show:

Element	What is visible
Board	A blue **five-column, four-row** grid
Pieces	Upright rectangular picture fragments
Reserve	Five face-down stacks positioned above the columns

Element	What is visible
Input	Dragging and swapping, including an illustrated exchange between distant cells
Completion	A demonstrated **2×2 picture** assembled from four fragments
Assistance	A lightbulb control with a displayed inventory count

One image illustrates a diagonal exchange between row 1, column 2 and row 3, column 5. This supports distant swapping as an intended interaction; it does not establish that every possible swap is legal under every condition. [6, 7]

A representative example is a flower photograph split into four pieces. The player recognizes the upper-left, upper-right, lower-left, and lower-right portions, brings them into the correct arrangement, and completes the image. Official media then illustrates new cards descending toward opened cells, including cards turning from their backs to their picture faces. [8, 9]

The distinction from ordinary identical-symbol matching is useful: **the relationship is positional**. Two fragments can belong to the same picture without being interchangeable. Recognizing a shared subject is only part of identifying the correct arrangement.

2.2 What is—and is not—established about the rules

The developer explicitly advertises **untimed play**, and the Android listing explicitly advertises **offline, single-player play**. A customer review also reports unlimited moves, but that is weaker evidence than a developer specification covering every mode. [1, 4]

The exact movement system remains incompletely documented:

- Whether every individual fragment can exchange with every other fragment.
- Whether connected fragments always move as a rigid group.
- Whether connected groups can be separated.
- How a multi-cell group displaces differently shaped occupied areas.
- Whether existing pieces fall before replacement cards enter.
- Whether stock is fixed separately for each column.
- Whether automatic completions can cascade after a refill.
- Whether the win condition requires exhausting all stock or satisfying another target.

These are substantial rules. They determine whether the player is mainly recognizing and rearranging images or solving a deeper problem of space and order.

2.3 How the game evolves

The evidence does **not** support a simple progression where boards continually get larger.

Three inspected third-party video thumbnails show the following states:

Displayed state	Visible board	Additional visible UI
Hard 15	5×5	Wand inventory 2; bulb inventory 3
Hard 138	6×6	Wand video offer marked +2; bulb inventory 3
Level 248	4×4	Wand inventory 1; bulb inventory 3

These are thumbnail observations, not verified playthroughs or universal level configurations. Nevertheless, the smaller board shown at a later level is a reason to avoid claiming that difficulty increases simply by expanding the grid. [10, 11, 12]

My design interpretation is that several variables could produce different experiences:

- More simultaneous fragments increase visual search.
- Larger or awkward partial images can increase spatial demands.
- Similar artwork increases recognition difficulty.
- Hidden partners increase uncertainty.
- Clear location and stock order could create planning demands, if the actual refill rules make those choices consequential.

Those variables should be evaluated separately. A 6×6 board can be visually busy without requiring much foresight. A 4×4 board can be strategically demanding if a small number of choices strongly affects what becomes available.

2.4 Helpers and performance feedback

The lightbulb is visible in official media, while the wand appears in the inspected thumbnails. An October Apple reviewer describes the wand as supplying needed material and completing a random picture. That is a useful functional report, but its exact target selection and current behavior were not independently reproduced. Other Apple reviewers describe viewing or enlarging finished images after a level. [1]

An Android reviewer mentions points associated with a jet-like element and grades in **Time, Moves, and Combo** boxes. The score equations, grade thresholds, and reward conversion remain unverified. An elapsed-time statistic would be compatible with untimed play; it would not establish a countdown. [4]

These suggest two possible mastery systems:

1. **Completion:** enjoying the finished picture.

2. **Performance:** improving how efficiently the picture was completed.

They can coexist well, but the second requires understandable feedback. A grade has little instructional value if the player cannot tell what produced it or what it affects.

2.5 Seasonal progression

Jigsaw Drop already has a progression layer beyond numbered levels.

The official **Hallow Waltz** event describes puzzles of different difficulties, hidden stories, illuminated fragments, **pumpkin tokens**, and a larger panorama to assemble. Its headline also advertises daily challenges. Exact token payouts, milestone thresholds, entry requirements, and the full event schedule were not established. [13]

This changes the improvement discussion. “Add seasonal collections” would duplicate something already present.

The more useful questions are:

- Does an ordinary puzzle clearly communicate its event contribution?
- Can the player see the next attainable milestone?
- Is the finished panorama worth revisiting?
- What persists after the event?
- Are completed pictures easy to find again?

The existence of a collection objective and the quality of its payoff are separate issues.

3. Picture Blast Solitaire

3.1 Core interaction and board variation

Picture Blast's official material describes swapping picture fragments, completing artworks, clearing finished images, and revealing more cards. The publisher advertises hundreds of handcrafted levels and picture subjects including animals, nature, flowers, and travel. "Handcrafted" is the publisher's description, not an independently audited production method. [5]

Current promotional images show different layouts:

Promotional example	Visible arrangement
Level 3	A 5×5 tableau of butterfly halves
Level 16 — Special	A 5×5 tableau of face fragments
Level 22 — Special	A 6×6 tableau of nail-art fragments

These are advertised states rather than a verified onboarding sequence. They show that a fixed "always 6×6" description would be inaccurate. [14, 15, 16]

The butterfly and face examples emphasize reconstructing left/right relationships. Other inspected media uses top/bottom relationships and larger multi-cell pictures. The same basic interaction can therefore produce different recognition and placement tasks.

3.2 The counters need careful interpretation

The current face-board image displays:

- A card icon with **0/30**.
- A coin balance of **400**.
- Face-down decks above the tableau.

The image does not establish whether "30" means cards, pictures, or another progress unit. Likewise, 400 is a displayed balance, not evidence that a level awards 400 coins or that a booster costs 400 coins. [15]

This is a small-looking distinction with large implications for an economy teardown. To reconstruct the economy, one must observe transactions: what changes after a clear, after a level, after a booster, and after a reward claim.

A screenshot of a balance cannot provide that information.

3.3 Linked pieces and exact movement

A current Google Play reviewer describes two- and four-piece pictures and says pieces remain together after linking. That supports investigating connected-group behavior, but does not settle how groups move into occupied areas or whether they can be separated. [3]

The unresolved questions are similar to Jigsaw Drop's:

- Which swaps are legal?
- What becomes one movable object?
- How are overlapping destinations resolved?
- What determines the next revealed piece?

- Can a player make an irreversible mistake?
- How does the game identify a blocked board?

Until those are observed, it would be premature to present a precise search-space model or claim that one game has demonstrably deeper planning than the other.

3.4 Boosters and combo feedback

The publisher's Level 7 image shows a 6×6 butterfly board, a progress bar, **Combo 7**, and two assistance controls:

- Shuffle arrows with an inventory of **2**.
- A lightbulb with an inventory of **7**.

Those are stock quantities, not verified prices. The combo label also does not reveal whether combos depend on time, successive completions, automatic cascades, or another condition. [17]

Separately, the official release history names a **Glass Booster**. Its precise effect is not described in the inspected note. Inferring "reveals a hidden card" or "magnifies the board" from that name would be speculation. [2]

For design analysis, these assistance types need to be distinguished. A hint supplies information; a shuffle changes the arrangement; a removal tool can bypass a dependency. Each has a different relationship to skill and fairness.

3.5 Progression outside the board

Picture Blast has the more visibly layered progression structure in the inspected material.

Level path. The publisher's home-screen image shows numbered nodes 17–24, differently styled card nodes, and a **Hard** label on the Play button. It also shows **Weekly Story, Home, and Collection** navigation. The node icons alone do not establish a complete taxonomy of level mechanics. [18]

Collection. Another publisher image shows a partially revealed 6×6 picture: 21 positions revealed and 15 still covered in that particular state. This supports a visual collection-completion layer, but not a universal "36 levels per collection" formula. [19]

Story Mode. Current promotional art presents a romance sequence involving a shopper and a security guard, followed by a dinner scene. That establishes narrative presentation; it does not establish branching dialogue, relationship statistics, renovation, or paid choices. [20]

3.6 How the product itself has evolved

The official iOS history provides two meaningful feature milestones:

Release	Confirmed additions
1.3.0 — 12 August 2026	Coins, revised win screen, collectible Memory Cards in the main menu, Glass Booster
1.4.0 — 25 September 2026	Daily Streak and Daily Challenges
Subsequent updates	Additional levels and fixes

This documents a move from the core picture-clearing loop toward currency, collection, and scheduled return activities. It does not disclose exact earning rates, prices, card thresholds, or streak-reset rules. [2]

My interpretation is that these systems address different time horizons:

- **Picture completion:** immediate satisfaction.
- **Level completion:** a short-session milestone.
- **Collection:** durable progress.
- **Daily challenge:** a reason to return.
- **Streak:** continuity across days.
- **Story:** curiosity about a subsequent reveal.

The opportunity is to make them reinforce one another. Adding more independent rewards could increase clutter without strengthening the reason to play.

3.7 Later-game friction

Public customer accounts raise image repetition, difficulty spikes, recovery-tool use, and technical interruptions. One Google Play reviewer describes repeated artwork; another describes reliance on help ads on difficult levels while also saying a previous reward-ad problem had been fixed. These are qualitative signals, not measurements of how frequently each problem occurs. [3]

The important distinction is between **new images** and **new decisions**.

A new butterfly can refresh the visual search. A different dependency between clears can change the puzzle. A sustainable content strategy should understand which kind of novelty it is supplying.

4. Monetization and resource economies

4.1 What is confirmed

Both titles are free downloads with advertising declared in their store listings. The inspected public pages did not establish a current, complete catalog of paid offers or prices. I could not verify a current No Ads SKU, subscription, coin pack, pass, paid continue, or energy refill for either title. That is an evidence gap, not proof that every region or experiment lacks purchases. [1, 2, 4, 3]

The documented or visible resource categories are:

Resource	Jigsaw Drop	Picture Blast
Assistance inventory	Bulb and wand evidence	Shuffle and bulb controls; named Glass Booster
General currency	Complete general-currency system unverified	Coins confirmed
Event currency	Halloween pumpkin tokens confirmed	Complete event-currency system unverified
Collectible progress	Seasonal panorama/postcard evidence	Memory Cards and Collection confirmed
Exact sources and sinks	Incomplete	Incomplete
Paid randomized acquisition	Unverified	Unverified

Coins do not automatically imply a coin shop. Collectible cards do not automatically imply randomized packs. A seasonal token does not automatically imply premium currency.

4.2 Advertising is the clearest commercial mechanism

Jigsaw reviewers report ads between levels and ads associated with assistance, while disagreeing about how intrusive they are. Picture Blast reviewers report reward/help advertising and, in some cases, interruptions during play. These reports do not establish a universal cadence or ad duration. [1, 4, 3]

From a design perspective, the location of an ad matters as much as its frequency.

A player is maintaining a mental map of fragments and possible matches. An interruption during that process can impose a reorientation cost. An interruption after a completed board occurs at a natural boundary.

Rewarded assistance introduces a second issue: **does the player understand it as optional help, or as the only possible continuation?**

Those are very different experiences even if the advertising implementation is identical.

4.3 "Requires a booster" is a claim that needs testing

A player who feels stuck might be facing:

1. A solvable board whose next move is difficult to notice.
2. A solvable board requiring preparatory moves.
3. A dead end caused by an earlier decision.
4. Missing information about hidden pieces.
5. A genuinely unsolvable state.
6. A technical failure.

Reviews cannot reliably distinguish those explanations.

That is why I would not infer deliberate manipulation or guaranteed unwinnable levels from complaints alone. The correct investigation is to capture the board, reproduce the rules, and determine whether a winning route exists.

No reviewed public evidence supports reliable estimates of revenue, payer conversion, retention, ad impressions per user, or lifetime value.

5. Social systems and persistence

The visible retention emphasis is individual: levels, completed pictures, collection progress, and scheduled activities.

Jigsaw explicitly presents itself as single-player and offline. That does not establish that every event, reward claim, or advertising function works offline. Picture Blast's complete offline behavior was not verified. [4]

For either exact product, I did not establish a title-specific implementation of:

- Friends or gifting.
- Guilds or teams.
- Chat.
- Trading.
- Live multiplayer.
- Competitive leagues.
- Public leaderboards.

- Cooperative picture assembly.
- Cross-device or cross-platform progression transfer.

This is a research status rather than a definitive absence claim. Generic publisher policies and store-page sharing buttons are insufficient evidence for those systems.

Persistence also needs its own testing. Local save, account linking, cloud synchronization, reinstall recovery, and cross-platform transfer are different capabilities. A game having hundreds of levels does not establish how safely that progress is stored.

6. What actually determines long-term depth?

This is the most consequential design question across both games.

A difficult visual search and a meaningful planning problem are different things.

If every exposed piece can be freely rearranged, every completion is beneficial, and moves are easily reversible, the experience may be primarily recognition and organization. That can be enjoyable and relaxing.

Planning emerges when a decision affects future options:

- Clearing one area reveals a useful fragment.
- A group occupies space needed elsewhere.
- Completing a small picture creates room for a larger one.
- An early placement preserves—or obstructs—a later route.
- The player can choose between an immediate clear and a more productive sequence.

Hidden information alone does not guarantee depth. If the consequence cannot reasonably be anticipated, a surprising refill can produce uncertainty without creating a satisfying decision.

The key test is:

> ***Can the player explain why completing picture A before picture B was a better choice?***

If the answer is usually “because A was the only match I noticed,” the skill is mostly recognition. If the answer is “because A exposed the fragment that enabled B and opened space for C,” the game is supporting planning.

The exact shipped rules need hands-on verification before assigning either game a definitive position on that spectrum.

Part II — Separate improvement proposal

The recommendations below are **proposed changes and experiments**, not claims that the games already implement them.

7. Shared priority: make the puzzle understandable and recoverable

7.1 Distinguish different kinds of “stuck”

The first investment should be a reliable model of solvability and recovery.

State	Appropriate response
A useful sequence exists but is difficult to see	Explain the first productive step
The player has made a recoverable mistake	Offer undo to a relevant state
No legal move exists	Provide clear recovery or restart
No winning route exists under the current rules	Recover without requiring an advertisement
The system has not determined solvability	Avoid declaring the board impossible

A solver timeout should remain inconclusive. “No immediate completion” should not be treated as proof of failure.

For authored or generated levels, preserve a known winning sequence where practical. The starting puzzle should have a valid solution independent of monetized assistance.

7.2 Explain what is actually moving

If linked pieces form a movable group, outline the whole group. Preview its destination footprint. Show which pieces will be displaced. Explain a rejected placement through the relevant rule.

If only a single fragment moves, the selection treatment should communicate that instead.

Support optional tap-to-select/tap-to-place input alongside dragging. Test finger occlusion, edge cells, dense boards, and tablet layouts.

These changes can improve the experience without making the puzzle easier. They reduce uncertainty about the interaction itself.

7.3 Give each assistance tool a clear purpose

I would separate assistance into understandable functions:

- **Undo:** reverse a decision.
- **Hint:** explain a productive next step.
- **Preview:** reveal additional information.
- **Shuffle:** change the arrangement.
- **Auto-complete:** finish or remove a specific obstacle.

Before consumption, show the effect, quantity, and acquisition method.

A first free demonstration can teach the tool. Basic recovery should remain available when an ad cannot load. Otherwise ad availability becomes an undocumented condition of whether the puzzle can continue.

8. Jigsaw Drop: build a stronger spatial puzzle and art collection

8.1 Make completed art worth keeping

Jigsaw already has seasonal collection objectives and player-reported post-level viewing. The opportunity is to connect them into a clear, persistent experience.

I would prioritize:

- Full-image viewing and zoom.
- Favorites.
- Themed albums.
- Clear indication of where an image was earned.
- Reliable creator, location, or subject information where available.
- An obvious route from the completion screen back to the art.
- Clear treatment of unfinished event progress when an event ends.

The objective is for the player to value the picture after its fragments have served their gameplay purpose.

8.2 Curate images for fragment readability

Artwork should be evaluated at two scales: the finished image and the individual fragment.

A strong full image can make a weak puzzle if most pieces become indistinguishable sky, foliage, or fabric. Conversely, distinctive landmarks and readable boundaries can make assembly satisfying.

I would assess each image against four questions:

1. Is the finished picture desirable?

2. Are its fragments legible at normal phone size?

3. Does its ambiguity create an intentional challenge?

4. Have rights, metadata, lettering, and image quality been reviewed?

A coherent “cabinet of wonders” direction could work well: botanical illustrations, wildlife, architecture, vintage travel, and unusual objects organized into purposeful collections. That is a design concept, not a claim about which theme would commercially outperform others.

8.3 Prototype optional spatial challenges

For deeper play, I would test a small authored mode built around **space and group shape**.

A prototype might use:

- A finite, visible piece set.
- Clearly defined connected groups.
- A limited staging area.
- Unlimited undo.
- An optional efficiency target after completion.

An illustrative puzzle: a wide group needs a two-cell gap. Two small pictures can be finished immediately, but only one clear creates the gap in a useful location. The player can see both consequences and discover the dependency.

The main risk is fiddliness. If the player understands the solution but must perform many administrative moves, the constraint has added labor rather than insight.

Keep the ordinary relaxed route available. Deeper optional puzzles should expand the audience's choices rather than turn every later level into a mandatory test.

9. Picture Blast: make exposure choices and progression coherent

9.1 Let the player plan around replenishment

My preferred prototype would emphasize **which picture to finish next**.

Test a visible preview of the next one or two pieces in the relevant stock. If the design uses a shared deck, show that queue. If it uses column-specific stock, show the relevant column previews.

The essential requirement is a single understandable rule.

For example, in a proposed puzzle:

- Finishing a butterfly reveals the missing half of a vase.
- Finishing the vase creates space for a four-piece portrait.
- Another available clear reveals material that cannot yet be used.

That sequence creates a reason to choose one completion over another.

The hint can then explain: "Complete the butterfly to expose the vase piece." It teaches the causal relationship instead of simply highlighting a match.

If previews make the game too obvious, deepen a few authored dependencies. Removing all information again would restore uncertainty, but might not restore interesting decisions.

9.2 Connect the existing rewards

Picture Blast already has Coins, Memory Cards, Collection, daily activities, streaks, and story presentation. I would first audit how these currently connect, then make the relationship visible.

A proposed structure could be:

Activity	Immediate reward	Longer-term purpose
Main level	Clear, understandable progress	Advance a themed image set
Set completion	Substantial full-art reveal	Unlock an album page or optional story scene
Daily puzzle	A distinct authored challenge	Predictable collection contribution
Return streak	A small transparent bonus	Encourage continuity without severe missed-day penalties

This is a redesign hypothesis, not the verified current economy.

Every reward moment should answer three questions: **What did I earn? Why did I earn it? What does it advance?**

9.3 Give Hard and Special levels different jobs

I would define the labels through the experience they promise.

- **Hard:** a familiar rule set requiring more planning.

- **Special:** a deliberate variation in objective, presentation, or reward.

A special level could assemble a larger final composition or reveal a story-relevant image. A hard level could require a longer dependency chain.

Similar-looking faces or patterns can make recognition demanding, but should not be the sole way to create difficulty.

9.4 Use story as an earned payoff

A lightweight illustrated story can make a picture emotionally meaningful without requiring a large narrative game around it.

Prototype one short chapter with a coherent sequence of images. Let the player revisit unlocked scenes and skip presentation when they want another puzzle.

Measure whether players voluntarily view or replay the story. Extra taps alone do not demonstrate attachment.

Romance, a travel diary, and a gentle mystery are plausible concepts to test. The research does not establish which would best fit the actual audience.

10. Improve monetization around continuity and value

Advertising

Test interstitials at completed-puzzle boundaries, after the result has been committed and the finished image has been shown.

For rewarded ads:

- Save the board before launch.
- Restore the same state after interruption.
- Deliver the promised reward exactly once.
- Handle repeated completion callbacks.
- Provide a fallback when no ad is available.

Measure interruption density as well as frequency. One ad per level can feel very different when levels take thirty seconds versus several minutes.

Purchases

I would test a clearly scoped one-time offer removing interstitial and banner ads. State separately whether optional rewarded ads remain.

Its recovery design must match its promise. An “ad-free” purchase would be confusing if ordinary continuation still routinely depended on watching ads.

Once the gallery is valuable, optional curated art collections are another plausible offer. Their appeal should be visible before purchase.

I would not choose an exact price from the available evidence. Price, entitlement, and conversion need market-specific testing.

Evaluation

Judge changes through sufficiently mature cohorts, including:

- Return rate.

- Completed puzzles per player.
- Ad-related exits.
- Reward failures.
- Help use and successful recovery.
- Purchase conversion and refunds.
- Contribution per player over the observation window.

More impressions in the first session are insufficient evidence of a healthier business.

11. Social opportunities should start small

Before building guilds or chat, I would test a reason to share a satisfying result:

- A daily puzzle with a common seed.
- A spoiler-free completion card.
- A private friend challenge link.
- Optional comparisons of efficiency.
- A community panorama built from individual contributions.

If efficiency is compared, distinguish assisted and unassisted results. Keep those competitive rules separate from the relaxed campaign.

A community activity should reinforce enjoyment of the puzzle. It should not require players to take on obligations before the core experience has earned that commitment.

12. Recommended order of work

Order	Work	What would justify continuing
First	Capture exact rules, reproduce states, validate solvability	Movement, clearing, refill, and recovery behave consistently
First	Fix ad-resume and reward reliability	Tested interruptions do not lose progress or strand attempts
Next	Improve selection, destination previews, and completed-art viewing	Better comprehension, fewer mistaken drops, more voluntary art viewing
Next	Prototype spatial challenges for Jigsaw and exposure planning for Picture Blast	Players can predict consequences and enjoy choosing between alternatives
Then	Clarify collection/story rewards and test an ad-free offer	Stronger repeat use and acceptable contribution
Later	Add sharing or community activity	Players already want to share the puzzle experience

If I were choosing the first two gameplay prototypes, I would build **a small, fully visible spatial puzzle for Jigsaw Drop** and **a deterministic, previewable clearing sequence for Picture Blast**. Both would have unlimited undo and optional mastery goals. The test would be whether players notice and enjoy meaningful alternatives—not simply whether the new levels take longer to finish.
